

# 2014 Kentucky Small-Grain VARIETY PERFORMANCE TEST

B. Bruening, R. Curd, S. Swanson, J. Connelley, G. Olson, A. Clark, and D. Van Sanford, Plant and Soil Sciences

[www.uky.edu/ag/WheatVarietyTest](http://www.uky.edu/ag/WheatVarietyTest)

The 2014 soft-red winter-wheat growing season ended with Kentucky farmers harvesting 530,000 acres of the 630,000 acres planted, for a total production of 37.1 million bushels of grain. An average yield of 70 bushels per acre was recorded (Table 1). The acreage not harvested for grain was primarily used for forage production and cover cropping.

Small-grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Table 2). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small-grain commodity had at least one trial conducted in that region for that commodity.

The objective of the Kentucky small-grain variety performance test is to evaluate varieties of wheat, oat, barley, triticale and cereal rye that are commercially available or may soon be available to Kentucky farmers. New varieties continually are being developed by agricultural experiment stations and commercial firms. Annual evaluation of small-grain varieties and selections provides farmers, seed producers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Because weather, soil, and other environmental factors may alter varietal performance from one location to another, seven tests were conducted at seven locations throughout the state (Table 2). In addition, a wheat test for varietal differences in forage potential and straw yields were conducted at one location.

## Experimental Methods

One hundred twelve entries were evaluated under both conventional and no-till cultural practices. No-till tests were grown at four locations, and conventional tests were grown at three locations. The experimental design was a randomized complete block. The tests had four replications per entry, and the data presented are the average response from the four replications.

The plots were planted with specially built multi-row conventional and no-till cone seeders. Conventional test plots consisted of six rows to form a plot 4 feet wide and 15 feet long, which was later trimmed to 12 feet in length. No-till plots consisted of seven

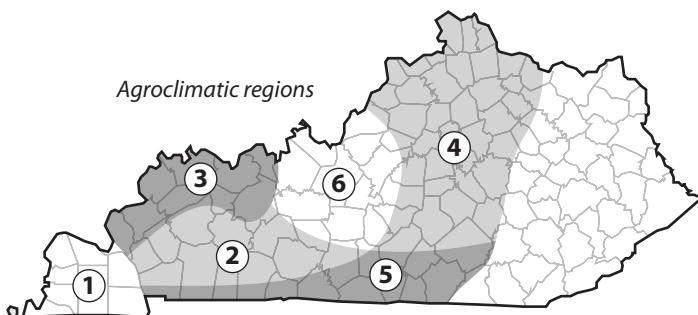

rows to form a plot 5 feet wide and 25 feet long, which was later trimmed to 20 feet in length. Plots were harvested with a small plot combine. The preceding crop for all tests was corn.

Tests were conducted using intensive management practices. Typical herbicide applications included a spring application for broadleaf control and a fall preplanting burn-down (no-till tests only) application. Fungicides were applied in the spring on all but two (disease rating) tests. An insecticide for aphid control was typically applied in the fall and spring. Nitrogen was applied in a February/March split application at a rate of approximately 30/60 pounds per acre (conventional tests) or 40/70 pounds per acre (no-till).

**Table 1. Wheat Acreage Harvested and Yields (bu/ac) in Kentucky, 2012-14.\***

2014		2013		2012	
Harvested	Yield	Harvested	Yield	Harvested	Yield
530,000	70	610,000	75	470,000	62

\*July 1, 2014, National Agricultural Statistics Service.

**Table 2. Agroclimatic Regions of Kentucky Small-Grain Variety Tests.**

Region	Location	Cooperator	Crop Tested
1 Purchase	Ballard Co.	Tom Miller	No-till wheat
2 Western Coal Field	Caldwell Co.	Princeton Research and Education Ctr.	No-till wheat, triticale, barley
3 Ohio Valley	Henderson Co.	David Alexander	No-till wheat
4 Bluegrass	Fayette Co.	Kentucky Ag. Exp. Station	Wheat*, oat, forage tests
5 Southern Tier	Logan Co. Trigg Co.	Don Halcomb Ben Cundiff and Barry Alexander	Wheat*
6 North Central	Nelson Co.	Homestead Farms & George McCain	No-till wheat

\* Conventional tillage.

The forage test was planted using conventional tillage and was harvested using a small plot forage combine at the soft-dough stage. Straw yield was measured using a small plot forage combine following grain harvest in the Bluegrass Region test.

## Characteristics Evaluated

Grain yields were calculated from the weight of grain from each plot and reported in bushels per acre (bu/ac) based on 60-pound, 48-pound, and 32-pound standard bushel weights for wheat, barley, and oats, respectively at 13.5 percent moisture content. Test weights (lb/bu) were determined using a HarvestMaster Classic GrainGage and adjusted to 13.5 percent moisture. Lodging was reported as the percentage of plant lodging at maturity; winter survival was reported as the percentage of survival after spring green-up. Winter survival was 100 percent for all locations except Princeton, KY. Plant height was measured in inches from the soil surface to the top of the grain head. Heading dates were reported as the day an estimated 50 percent of the heads had extended above the flag leaf collar. Disease ratings (leaf blotch [*Septoria tritici* and *Stagonospora nodorum*], powdery mildew, and fusarium head scab ratings) were recorded at the Logan County (non-fungicide) test. Forage and straw yields are expressed as dry matter in tons per acre.

## Results and Interpretation

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data at multiple locations from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a multi-year average of another variety because it is possible that results in one of the other years were extremely good or poor and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location or within the same analysis across locations. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently outyields another over a period of several years, the chances are that the differences are real. LSD (least significant difference) values are listed at the bottom of table columns to indicate whether differences are statistically significant.

Lodging data are difficult to interpret. A high-yielding variety should not necessarily be downgraded because of a high percentage of lodging for a given year at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a

greater degree of lodging than do farmer fields. It also should be emphasized that a variety reported to be 50 percent lodged does not imply that only 50 percent of the grain could be harvested. With good equipment, most of the grain can often be saved.

Kentucky's climate and soils are well-suited for the production of high-quality soft-red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yield potential, straw strength and yield, height, heading date, grain quality, disease resistance, and forage potential are important in choosing a variety.

Winter barley is less winter-hardy than winter wheat but more hardy than winter oats. The degree of winter-hardiness, straw strength, and maturity are important characteristics when choosing a variety. Barley (hulless and hulled) variety performance data are presented in tables 14 and 15. Oat forage, grain, and straw yield data are presented in Table 18.

## Test Conditions

Cool temperatures and wet conditions during October delayed planting throughout much of the state. The 2014 Kentucky small-grain variety tests were planted from October 11 to October 23. Cold temperatures from November through April delayed green-up and growth. Normal rainfall in April and May minimized disease pressure throughout the state. Visual head scab symptoms were minor, but reports of high vomitoxin (DON) levels were reported in growers grain at harvest, which was likely the result of atypical late head scab infection. Normal conditions in May and June accelerated maturity and dry-down, but harvest maturity was delayed by approximately one week due to the prolonged winter temperatures.

## Acknowledgments

Thanks to the following individuals for their support and assistance with this project: Kentucky Small Grain Growers Association, Don Halcomb, Brian Rouse, Ben Cundiff, Barry Alexander, David Fourqurean, Tom Miller, David Alexander, George McCain, Homestead Farms, Cam Kenimer, Chad Lee, Dennis Egli, Marcy Rucker, Mike Smith, Dakota Smith, Bobby Orange, Joe Williams, Scott Peek, Michael Carter, Shawn Wood, Jackie Harper, Benjamin Abourjeily, and the UK Wheat Science Group.

All disease ratings taken in Logan County near Adairville, KY.

Disease rating scale: 1 = resistant; 9 = susceptible.

Powdery mildew: Disease was present at low levels.

\* Indicates susceptibility

Key: Fusarium head blight (head scab); Septoria tritici leaf blotch and Stagonospora nodorum leaf blotch
