

2014 Timothy and Kentucky Bluegrass Report

G.L. Olson, S.R. Smith, G.D. Lacefield, and T.D. Phillips, Plant and Soil Sciences

Introduction

Timothy (*Phleum pratense*) is the fourth most widely sown cool-season perennial grass used in Kentucky for forage—after tall fescue, orchardgrass, and Kentucky bluegrass. It is a late-maturing bunchgrass that is primarily harvested as hay, particularly for horses. It also can be used for grazing or wildlife habitat.

Management is similar to that for other cool-season grasses. Harvesting at the mid- to late-boot stage is needed to assure good yields and high forage quality. The quality of timothy declines more rapidly after heading than other cool-season grasses. In Kentucky, timothy behaves like a short-lived perennial, with stands usually lasting two to three years.

Kentucky bluegrass (*Poa pratensis*) is a high-quality, highly palatable, long-lived pasture plant with limited use for hay. It tolerates close, frequent grazing better than most grasses. It has low yields and low summer production and becomes dormant and brown during hot, dry summers. Kentucky bluegrass is slow to establish.

This report provides maturity and yield data on timothy and Kentucky bluegrass varieties included in yield trials in Kentucky. Tables 10 and 11 show summaries of all timothy and Kentucky bluegrass varieties tested in Kentucky for the last 15 years. The UK Forage Extension Web site, at www.uky.edu/Ag/Forage, contains forage variety testing reports from Kentucky and surrounding states and a large number of other forage publications.

Considerations in Selection

Local adaptation and seasonal yield.

Choose a variety that is adapted to Kentucky, as indicated by good performance across locations in replicated yield trials, such as those presented in this publication. Also, look for varieties that are productive in the desired season of use, whether for hay or grazing. Later-maturing varieties are desirable when timothy is grown in pure stands for hay; early maturing varieties provide a better fit when timothy is grown in mixtures with legumes.

Seed quality. Buy premium-quality seed that is high in germination and purity and free from weed seed. Buy certified seed or proprietary varieties of seed of an improved variety. An improved variety is one that has performed well in independent trials such as those reported in this publication.

Description of the Test

Data from six studies are reported. Timothy varieties and Kentucky bluegrass varieties were sown at Lexington in 2011, 2012, and 2013 as part of the

University of Kentucky Forage Variety Testing Program. The soil at Lexington (Maury) is a well-drained silt loam and is well-suited for timothy and bluegrass production. Seedlings were made at the rate of 8 pounds per acre for timothy and 15 pounds per acre for Kentucky bluegrass into a prepared seedbed with a disk drill. Plots were 5 feet by 20 feet in a randomized complete block design with four replications with a harvested plot area of 5 feet by 15 feet. Nitrogen was applied at 60 pounds per acre of actual nitrogen in March, May, and August. The test was harvested using a sickle-type forage plot harvester leaving a 3-inch stubble to simulate a hay management system. The first cutting was harvested when spring growth of most varieties had reached the mid- to late-boot stage. Subsequent harvests were taken when forage growth was adequate for harvest. Fresh weight samples were taken at each harvest to calculate dry-matter production. Establishment, fertility (P, K, and lime based on regular soil tests), weed control, and harvest were managed according to University of Kentucky Cooperative Extension Service recommendations.

¹ DEP is departure from the long-term average.

² 2014 data is for the ten months through October.

Results and Discussion

Weather data for Lexington are presented in Table 1.

Maturity ratings (see Table 2 for maturity scale) and dry-matter yields are reported in tables 3 through 8. Yields are given by harvest date for 2014 and as total annual production. Stated yields

are adjusted for percent weeds; therefore, value listed is for crop only. Varieties are listed by descending total production. Experimental varieties, listed separately at the bottom of the tables, are not available commercially.

Statistical analyses were performed on all data to determine if the apparent

differences are truly due to varietal differences. Varieties not significantly different from the top variety in the column are marked with one asterisk (*). To determine if two varieties are significantly different, compare the difference between them to the Least Significant Difference (LSD) at the bottom of that column. If the difference is equal to or greater than the LSD, the varieties are significantly different when grown under those conditions. The Coefficient of Variation (CV) is a measure of the variability of the data and is included for each column of means. Low variability is desirable, and increased variability within a study results in higher CVs and larger LSDs.

Tables 9 and 10 summarize information about distributors and yield performance for Kentucky bluegrass and timothy varieties included in tests in this report. Varieties are listed in alphabetical order, with the experimental varieties at the bottom. Remember that experimental varieties are not available for farm use. In tables 9 and 10, an open block indicates the variety was not in that particular test (labeled at the top of the column); an “x” in the block means the variety was in the test but yielded significantly less than the top-yielding variety. A single asterisk (*) means the variety was not significantly different from the highest-yielding variety, based on the 0.05 LSD. It is best to choose a variety that has performed well over several years and locations.

Tables 11 and 12 are summaries of yield data of commercial varieties for Kentucky bluegrass (1996-2014) and timothy (2000-2014) that have been entered in the Kentucky trials. The data are listed as a percentage of the mean of the commercial varieties entered in each specific trial. In other words, the mean for each trial is 100 percent—varieties with percentages over 100 yielded higher than average and varieties with percentages less than 100 yielded lower than average. Direct, statistical comparisons of varieties cannot be made using the summary tables 11 and 12, but these comparisons do help to identify varieties for further consideration. Varieties that have performed better than average over many years and at several locations have stable

Table 2. Descriptive scheme for the stages of development in perennial forage grasses.

| Code | Description | Remarks |
|---|--|--|
| Leaf development | | |
| 11 | First leaf unfolded | Applicable to regrowth of established (plants) and to primary growth of seedlings. |
| 12 | 2 leaves unfolded | Further subdivision by means of leaf development index (see text). |
| 13 | 3 leaves unfolded | |
| • | ••••• | |
| 19 | 9 or more leaves unfolded | |
| Sheath elongation | | |
| 20 | No elongated sheath | Denotes first phase of new spring growth after overwintering. This character is used instead of tillering, which is difficult to record in established stands. |
| 21 | 1 elongated sheath | |
| 22 | 2 elongated sheaths | |
| 23 | 3 elongated sheaths | |
| • | ••••• | |
| 29 | 9 or more elongated sheaths | |
| Tillering (alternative to sheath elongation) | | |
| 21 | Main shoot only | Applicable to primary growth of seedlings or to single tiller transplants. |
| 22 | Main shoot and 1 tiller | |
| 23 | Main shoot and 2 tillers | |
| 24 | Main shoot and 3 tillers | |
| • | ••••• | |
| 29 | Main shoot and 9 or more tillers | |
| Stem elongation | | |
| 31 | First node palpable | More precisely an accumulation of nodes. Fertile and sterile tillers distinguishable. |
| 32 | Second node palpable | |
| 33 | Third node palpable | |
| 34 | Fourth node palpable | |
| 35 | Fifth node palpable | |
| 37 | Flag leaf just visible | |
| 39 | Flag leaf ligule/collar just visible | |
| Booting | | |
| 45 | Boot swollen | |
| Inflorescence emergence | | |
| 50 | Upper 1 to 2 cm of inflorescence visible | |
| 52 | ¼ of inflorescence emerged | |
| 54 | ½ of inflorescence emerged | |
| 56 | ¾ of inflorescence emerged | |
| 58 | Base of inflorescence just visible | |
| Anthesis | | |
| 60 | Preanthesis | Inflorescence-bearing internode is visible. No anthers are visible. |
| 62 | Beginning of anthesis | First anthers appear. |
| 64 | Maximum anthesis | Maximum pollen shedding. |
| 66 | End of anthesis | No more pollen shedding. |
| Seed ripening | | |
| 75 | Endosperm milky | Inflorescence green. |
| 85 | Endosperm soft doughy | No seeds loosening when inflorescence hit on palm. |
| 87 | Endosperm hard doughy | Inflorescence losing chlorophyll; a few seeds loosening when inflorescence hit on palm. |
| 91 | Endosperm hard | Inflorescence-bearing internode losing chlorophyll; seeds loosening in quantity when inflorescence hit on palm. |
| 93 | Endosperm hard and dry | Final stage of seed development; most seeds shed. |

performance; others may have performed well in wet years or on particular soil types. These details may influence variety choice, and the information can be found in the yearly reports. See footnotes in tables 11 and 12 to determine to which yearly report to refer.

Summary

Selecting a good timothy or Kentucky bluegrass variety is an important first step in establishing a productive stand of grass. Proper management, beginning with seedbed preparation and continuing throughout the life of the stand, is necessary for even the highest yielding variety to produce to its genetic potential.

The following is a list of University of Kentucky Cooperative Extension publications related to timothy and Kentucky bluegrass management. They are available from your county Extension office and are listed in the "Publications" section of the UK Forage Web site, www.uky.edu/Ag/Forage.

- Lime and Fertilizer Recommendations (AGR-1)
- Grain and Forage Crop Guide for Kentucky (AGR-18)
- Establishing Forage Crops (AGR-64)
- Timothy (AGR-84)
- Kentucky Bluegrass as a Forage Crop (AGR-134)
- Forage Identification and Use Guide (AGR-175)
- Establishing Horse Pastures (ID-147)

¹ Year trial was established.

² Use this summary table as a guide in making variety decisions, but refer to specific yearly reports to determine statistical differences in forage yield between varieties. To find actual yields, look in the yearly report for the final year of each specific trial. For example, the Lexington trial planted in 2004 was harvested three years, so the final report would be "2007 Timothy and Kentucky Bluegrass Report" archived in the KY Forage website at <www.uky.edu/Ag/Forage>. The '96 and '03 Lexington results are in the appropriate Tall Fescue Reports.

³ Mean only presented when respective variety was included in two or more trials.

⁴ Number of years of data.
