

# 2020 Kentucky Small Grain

## VARIETY PERFORMANCE TRIALS

B. Bruening, P. Shine, S. Swanson, J. Connelley, G. Olson, and D. Van Sanford, Plant and Soil Sciences

[www.uky.edu/ag/WheatVarietyTest](http://www.uky.edu/ag/WheatVarietyTest)

The 2020 soft red winter wheat growing season ended with Kentucky farmers harvesting approximately 390,000 acres of the 460,000 acres planted, for a total production of 28.5 million bushels of grain. An average yield of 73 bushels per acre was estimated by NASS (Table 1). The acreage not harvested for grain was primarily used for cover cropping and forage production. The NASS June estimate may however, have underestimated the effect of freeze damage on the wheat crop.

Small grain performance trials were conducted in six of the seven agroclimatic regions of Kentucky (Table 2). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity had at least one trial conducted in that region for that commodity.

The objective of the Kentucky small grain variety performance trials is to evaluate varieties of wheat, oat, barley, triticale, spelt, and cereal rye that are commercially available or may soon be available to Kentucky farmers. New varieties continually are being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides farmers, seed producers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Because weather, soil, and other environmental factors may alter varietal performance from one location to another, seven wheat trials were conducted at seven locations throughout the state (Table 2). In addition, a trial for varietal differences in wheat forage yield was conducted at one location.

### Experimental Methods

A total of 86 wheat entries were evaluated under either conventional or no-till cultural practices. No-till trials were grown at three locations, and conventional trials were grown at four locations. The experimental design was a randomized complete block. The trials had four replications per entry, and the data presented are the average response from the four replications.

The plots were planted with specially built multi-row conventional and no-till cone seeders. Conventional test plots consisted of six rows to form a plot 4 feet wide and 15 feet long, which was later trimmed to 12 feet in length. No-till plots consisted of

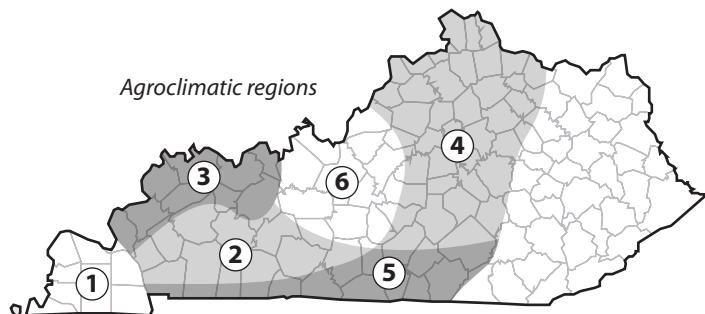

seven rows to form a plot 5 feet wide and 25 feet long, which was later trimmed to 20 feet in length. Plots were harvested with a small-plot combine. The preceding crop for all trials was corn.

Trials were conducted using intensive management practices. Typical herbicide applications included a spring application for broadleaf control and a fall preplanting burn-down (no-till trial only) application. Fungicides were applied in the spring on all but two (disease rating) trials. An insecticide for aphid

\*Conventional tillage.

control was typically applied in the fall and spring. Nitrogen was applied in a February/March split application at a rate of approximately 30/60 pounds per acre (conventional tests) or 40/70 pounds per acre (no-till).

The forage trial was planted using conventional tillage and was harvested using a small plot forage combine at the soft dough stage. Straw yields were not measured due to variable late tillering associated with freeze damage.

## Characteristics Evaluated

Grain yields were calculated from the weight of grain from each plot and reported in bushels per acre (bu/ac) based on 60-pound, 56-pound, 48-pound, and 32-pound standard bushel weights for wheat, cereal rye, barley, and oats, respectively, at 13.5 percent moisture content. Test weights (lb/bu) were determined using a HarvestMaster Classic GrainGage and adjusted to 13.5 percent moisture. Lodging was reported as the percentage of plant lodging at maturity; winter survival was reported as the percentage of survival after spring green-up. Winter survival was 100 percent for all wheat, barley, triticale, spelt, and cereal rye trials. Plant height was measured in inches from the soil surface to the top of the grain head. Heading dates were reported as the day an estimated 50 percent of the heads had extended above the flag leaf collar. Disease ratings: Septoria leaf blotch was recorded at the Logan County (non-fungicide) trial; leaf rust was rated at the Woodford County trial. Forage yields are expressed as dry matter in tons per acre. Plant canopy coverage (estimate of winter grazing potential or cover crop biomass) was measured using the Canopeo app on 1-14-2020 at the Woodford farm trial.

## Results and Interpretation

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data at multiple locations from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a multi-year average of another variety because it is possible that results in one of the other years were extremely good or poor and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location or within the same analysis across locations. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out yields another over a period of several years, the chances are that the differences are real. LSD (least significant difference) values are listed at the bottom of table columns to indicate whether differences are statistically significant.

Lodging data are difficult to interpret. A high-yielding variety should not necessarily be downgraded because of a high percentage of lodging for a given year at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials

normally have a greater degree of lodging than do farmer fields. It also should be emphasized that a variety reported to be 50 percent lodged does not imply that only 50 percent of the grain could be harvested. With good equipment, most of the grain can often be saved.

Kentucky's climate and soils are well-suited for the production of high-quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yield potential, straw strength and yield, height, heading date, grain quality, disease resistance, and forage potential are important in choosing a variety.

Winter barley is less winter-hardy than winter wheat but more hardy than winter oats. The degree of winter-hardiness, straw strength, and maturity are important characteristics when choosing a variety. Barley (hulless and hulled) variety performance data are presented in tables 15 and 16. Cereal rye, triticale, oat, and spelt variety performance data are presented in tables 17, 18, 19 and 20, respectively.

## Growing Conditions

Warm temperatures in early/mid October facilitated timely planting of a majority of the 2020 Kentucky wheat crop. Frequent rainfall during mid/late October slowed remaining planting. The 2020 Kentucky small grain variety trials were planted from October 5 to October 19. Cool temperatures in November slowed fall plant growth and development, particularly in late planted fields. Above average temperatures from December through mid-April accelerated growth and development. Reproductive growth was about one week ahead of normal. There were two freeze events which damaged Kentucky's wheat crop. An April 15th freeze caused damage to many wheat fields in west Kentucky, where the crop was often heading. Damage occurred in central Kentucky as well, where the crop was nearing boot stage. On May 9th a severe freeze event occurred in central Kentucky, severely damaging the crop which had already experienced damage from the April 15th freeze. Lower temperatures in May favored seed filling. Moderate temperatures and dry conditions favored timely harvest.

## Acknowledgments

Thanks to the following individuals for their support and assistance with this project: Kentucky Small Grain Growers Association, the Halcomb family, Brian Rouse, Brandon Hunt, Henry Sanger, Ben Rudy, Robert Rouse, Bruce and Jeremy Benson, Vicki Shadrick, Scott Peek, Shannon Rudd, Matt Peak, Cam Kenimer, Dennis Egli, Bobby Orange, Michael Carter, Shawn Wood, Jackie Harper, John Stanhope, and the UK Wheat Science Group.

\*Injury rating: 5 = severe, 1 = no injury (visual rating of chlorosis and necrosis recorded 3-16-20).

**Location:** Caldwell County (Princeton, KY)

**Planting date:** 10-15-19; conventional tillage.

**Harvest date:** 6-17-20; lodging = 0%.

Maximum labeled rate of 10-2/3 oz/A DimetricEXT (75% Metribuzin) applied 2-17-2020 (Feekes 4/5).

50% of plot area sprayed.

Test sustained minor/moderate freeze damage.
