

# 1997 Kentucky Small Grain Variety Trials

C.R. Tutt, C.S. Swanson, M. D. Elmore, and D.A. Van Sanford

In 1997, Kentucky farmers harvested 26 million bushels of soft red winter wheat produced on 500,000 acres. The average yield of 52 bu/a was 1 bushel less than the 1996 yield. Barley yields were 70 bu/a, 4 bushels less than the 1996 yields.

Small grain performance tests were conducted in six of the seven agro-climatic regions of Kentucky (Fig. 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley and wheat that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Since weather, soil, and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Fig. 1) in the state.

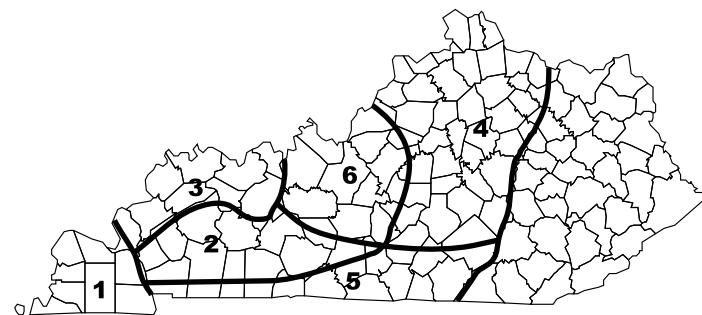

## Experimental Methods

The plots were planted with a specially built multi-row cone seeder. Each plot consisted of six rows to form a plot 4 feet wide, which was later trimmed to 10 feet in length. Each variety was grown in four

4. Bluegrass	Lexington	Kentucky Agricultural Experiment Station	Barley, Wheat
5. Southern Tier	Bowling Green	Western Kentucky University Farm	Barley, Wheat
6. North Central	Hopkinsville Shelbyville	Donnie & Duane Moore Mike Ellis	Barley, Wheat Wheat

Acknowledgement is made to the following individuals for their contributions to the bulletin: Bill Green, Mike Smith, Curt Judy, and Roy Catlett, County Extension Agents for Agriculture, for assistance in locating test sites and collecting data; D. Hershman for disease ratings; B. Zeng, X. Yang, B. Endsley, R. Baker, and J. Connolly for data collection; Mary Ann Kelley for text and table preparation; and Freddie Higgins for data analysis.

replications, and the data presented are the average response from the four replications of 40 square feet harvested with a small plot combine. Planting dates of all trials for the past three years are listed in Table 2.

In some instances, uncontrollable factors — such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years give a more accurate picture of varietal performance than do annual data.

## Results and Discussion

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a three-year average of another variety since it is possible that results in one of the other years were extremely good or poor, and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out-yields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be down-graded because of a high percentage of lodging for a given year at a

given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data since they will give a more accurate picture of varietal performance.

## 1997 Test Conditions

Favorable weather during October allowed for timely seeding of wheat and barley variety trials. November was cooler and wetter than normal. December, January, and February had normal precipitation with normal to above-normal temperatures. March was one of the wettest on record with above-normal temperatures. April and May continued wet but with below-normal temperatures. Having come through the winter with little or no winterkill, the trials grew rather poorly due to the wet, cool spring. However, the condition of the tests improved markedly as the season progressed. Diseases were very light at all locations with the exception of some wheat spindle streak and head scab infection. Overall, yields were little affected by diseases.

The Hopkinsville (Table 8) and Lexington (Table 6) trials were treated with fungicides to control fungal diseases. Tests at all other locations were untreated so varieties could be rated for disease resistance. However, there was little opportunity for disease ratings due to the overall light infections at the test locations.

## **Small Grain Varieties for 1998**

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of the small grain varieties are summarized in Tables 3 and 11.

### ***Soft Red Winter Wheat Varieties***

Kentucky's climate and soils are well suited for the production of high quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality, and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 4-9.

### ***Winter Barley Varieties***

Winter barleys are less winterhardy than winter wheat but more hardy than winter oats. The degree of winterhardiness, straw strength, and maturity are important characteristics when choosing a variety. Varietal performance data are presented in Tables 12-14.

### **Certified Seed**

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed that has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

Mean = 58.4 BU/A

CV = 13.28

LSD(0.05) = 3.7

<sup>1</sup>The CV is a measure of experimental error. The lower the CV the more reliable the results.<sup>2</sup>The LSD (Least Significant Difference) is the minimum difference required for two varieties to be significantly different from one another.<sup>3</sup>"Unauthorized propagation prohibited". Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.

<sup>1</sup>VS=VERY SUSCEPTIBLE; R=RESISTANT; MR=Moderately Resistant; S=SUSCEPTIBLE; MS=Moderately Susceptible;<sup>(--)</sup>=INSUFFICIENT OPPORTUNITY TO RATE IN PRESENCE OF DISEASE.

In general, varieties with a VS or S reaction to a given disease will not perform well if that disease becomes severe, while varieties rated R or MR will perform well in those situations. Varieties with an MS reaction will have an intermediate response.

<sup>2</sup>Rating of newly released varieties based on 1 yr. and 1 location.<sup>3</sup>Based on disease progress and final disease level. Ratings were made in 1995. Some selected varieties were rated in 1997.<sup>4</sup>Wheat spindle streak mosaic virus. 1997 ratings.<sup>5</sup>Disease pressure was not sufficient in 1997 to make ratings on all varieties. Data shown on the table are the 1995 ratings with some selected varieties rated in 1997.

TABLE 11 CHARACTERISTICS OF BARLEY VARIETIES TESTED IN 1997.

VARIETY	PROTECTED	SOURCE	RELEASE DATE	YIELD (BU/AC)	TEST WEIGHT (LB/BU)	LOGGING (%)	PLANT HEIGHT (IN.)	SURVIVAL (%)	HEADING DATE
CALLAO	YES	VIRGINIA	1994	82.0	47.3	5.8	33.8	100.0	28-APR
WYSOR	NO	VIRGINIA	1985	75.9	44.0	0.0	41.0	100.0	03-MAY
PAMUNKEY	YES	VIRGINIA	1993	73.1	45.5	0.8	38.3	100.0	28-APR
STARLING	YES	VIRGINIA	1993	72.3	42.9	8.3	39.8	100.0	03-MAY
MEAN =	75.8	BU/A							
CV =	11.3%								
LSD(0.05) =	5.9	BU/A							

MEAN = 75.8 BU/A

CV = 11.3%

LSD(0.05) = 5.9 BU/A

<sup>1</sup>The CV is a measure of experimental error. The lower the CV the more reliable the results.<sup>2</sup>The LSD (Least Significant Difference) is the minimum difference required for two varieties to be significantly different from one another.<sup>3</sup>"Unauthorized propagation prohibited." Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.
