New Web site feature: selection key to create subsets of summary Table 3—[description on page 4](#).

The Kentucky Soybean Performance Tests are conducted to provide an unbiased, objective estimate of the relative performance of soybean varieties in Kentucky. This information may be used by growers and seedsmen to aid in selecting varieties that will give the highest total production in a specific situation.

Eight soybean tests were planted in 1999 in Kentucky. The test locations are shown below. Soil types, planting dates, and other information are shown in Table 1.

Methods

All tests were planted in a randomized complete block design by maturity group. The conventional tests (all entries, Tables 4-7) had two replications (plots) of each variety. The soybean cyst nematode (SCN) and Roundup Ready (Roundup Ready is a registered trademark of Monsanto Company) tests

had three replications. The individual plots were 20 feet long and 6 rows wide with 15 inches between rows (seeding rate five to six viable seeds per foot of row). All plots were treated with herbicides and maintained as weed-free as possible. The SCN test was planted at a site infested with soybean cyst nematode. Only varieties with some genetic resistance to SCN and susceptible check varieties were tested at this site.

No preplant herbicides were used on the Roundup Ready test. This test was treated three times with Roundup Ultra in order to control yellow nutsedge.

Harvesting was done with a small plot combine according to maturity; thus, several harvests were made at each location. Sixteen feet of the center rows were harvested from the plots. No allowances were made for soybeans that may have been lost because of combining or shattering.

Yield—Yield is reported in bushels per acre adjusted to 13% moisture.

Lodging—Lodging is rated on a scale of 1 to 5, where 1 = almost all plants erect; 2 = all plants over slightly or a few down; 3 = all plants over moderately or 25% down; 4 = all plants over considerably or 50 to 80% down; 5 = all plants over badly.

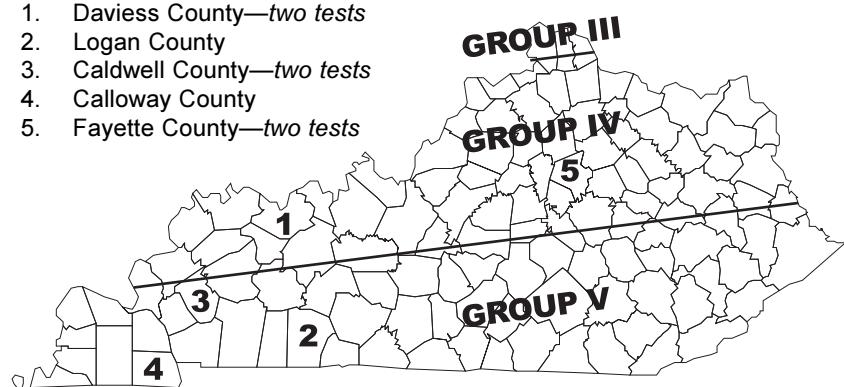

Maturity date—A variety is considered mature when 95% of the pods have turned their normal mature color. One to two weeks of good drying weather will be needed beyond the date given before the beans will be ready to combine. Maturity dates were recorded at the Fayette County and Caldwell County locations.

Plant height—Plant height was measured in inches from the soil surface to the tip of the main stem.

Soybean cyst nematode (SCN)—SCN populations were determined at planting and at harvest by measuring SCN egg densities in plots. Egg densities, reported as the number of eggs/100 cubic centimeters of soil (about $\frac{1}{4}$ pint of soil), were determined from soil samples consisting of ten 6-inch deep soil probes from the center two rows of each plot. Soil was thoroughly mixed. Cysts were extracted from two 100 cubic centimeter soil samples from each plot by wet sieving. Eggs

Location of the 1999 Kentucky Soybean Tests

1. Daviess County—two tests
2. Logan County
3. Caldwell County—two tests
4. Calloway County
5. Fayette County—two tests

Fayette Co. Roundup Ready	Lexington Exp. Station		Maury Silt Loam	5/11	P 372 K 197 pH 6.2	100 lb KCl	10/26
Daviess Co. SCN	Joe Elliott and Sons	Wayne Mattingly	Calloway Silt Loam	5/26	P 112 K 151 pH 7.0	200 lb 6-15-40	10/25

¹ No-till double cropped after wheat² Amount per acre.³ Based on 30-year average⁴ Data not published due to excessive variability caused by the drought.

were freed from cysts by crushing the cysts. Eggs were then stained and counted. The two egg counts from each plot were averaged to give a single egg density per plot. These data were provided by Don Hershman and Debbie Morgan of the Soybean Cyst Nematode Laboratory at Princeton, Kentucky.

Interpretation

An important step in profitable soybean production is selecting good quality seed of the best varieties for your management system. The Kentucky Soybean Performance Tests are conducted to provide information useful in making this selection.

Performance of soybean varieties is affected by many factors, including year, location, soil type, and time of planting. A particular soybean variety is adapted for full-season growth in a band approximately 100 miles wide from north to south (see map, page 1). Thus, the best variety in Northern Kentucky may not be the best in southern areas. For this reason, the Kentucky Soybean Performance Tests are conducted at several locations in the major soybean-producing areas of the state. The yields as reported in this publication should be used for relative comparisons; actual yields on a grower's farm may be different.

Performance of the soybean varieties will vary from year to year and location to location, depending on adaptability, weather conditions, and management. The performance data presented in Table 3 has been averaged across years and locations. **Performance of a variety across a period of years and at several locations in the state is the best indicator of**

its production potential. (See *Agronomy Notes*, Volume 21, No. 3, "Using Performance Test Results in Soybean Variety Selection in Kentucky.")

Small differences in yield are usually of little importance. The yield of two varieties at a single location can differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture), although the inherent yielding ability is the same. To decide if an observed yield difference is real, use the least significant difference (LSD) values cited at the bottom of the tables. The significance level used in the tables is 0.10. If the difference in yield is greater than the LSD value, you can be reasonably certain that the entries actually do differ in yielding ability. Within a maturity group, shaded yields are not significantly different (0.10 level) from the highest yielding cultivar (bold data) of that maturity group and year column.

Yield is only one factor to consider in selecting a variety for your production system. Maturity, lodging resistance, disease resistance, and time and equipment availability are other factors that need to be considered. Weed control and the economic management of weeds is an additional factor to consider with the advent of Roundup Ready soybeans.

The data provided have been divided into maturity groups. Due to weather patterns at a location, maturity alone can affect yield; this impact will be reflected by large differences in the maturity group averages. Selecting varieties from several maturity groups can reduce the impact of these maturity group fluctuations. (See *Agronomy Notes*, Volume 25, No. 3, "Growing

Soybean Varieties from Multiple Maturity Groups Can Reduce Yearly Yield Volatility.”)

The date of a 50% chance of a fall killing frost is important in determining which variety you select to plant. The dates presented in Table 1 are average dates over a long term. Actual dates will vary from year to year. For the date of a one-year-out-of-ten chance of a fall killing frost, subtract 13 to 18 days from the dates in Table 1. For maximum yield, a variety must mature before the first killing frost in the fall. Maturity dates of varieties are listed for the Fayette County and Caldwell County locations and in the combined summary table.

If you have soybean cyst nematode problems, a resistant variety should be used in your production system with a recommended crop rotation program. (See Kentucky Cooperative Extension Service publication *Soybean Cyst Nematode* (PPA-3), available at your county Extension office). The level of SCN infestation as well as the SCN race can be determined through the SCN laboratory at Princeton. **Test your fields.** Contact your county Extension office for more information on collecting and submitting samples. The importance of resistant varieties has increased as the number of acres affected by SCN has increased. SCN occurs in 32 western Kentucky counties representing 90% of the soybean acreage. Low levels of SCN show few visible symptoms but can cause yield losses of up to 25%. When evaluating the performance of resistant varieties in the SCN-infested location, note the change in SCN egg numbers as well as the yield presented in the SCN table.

Soybean mosaic virus (SMV) may cause yield loss if soybean plants are infected prior to flowering. Due to the timing of insect populations which transmit the disease, double-cropped soybeans are more likely to be affected in Kentucky. Planting SMV-resistant varieties will prevent this possible yield loss. Contact individual seed companies for the SMV resistance ratings of their varieties.

Growing Conditions and Special Circumstances

Growing conditions across Kentucky in 1999 can be summed up in one word: drought. On June 5 the three soybean-growing regions of Kentucky were already classified as being in mild or moderate drought. All three regions entered the severe drought category between August 14 and 28, with the central and Bluegrass areas reaching the extreme drought category between September 4 and 11. From April 1 to the end of the growing season Kentucky locations ranged from 4 to 15 inches below normal rainfall. As a consequence, test yields were low and the variability across

a field was heightened. Variability was further increased by rapid and erratic shattering. **Test and/or individual maturity group data at a location are not presented if the coefficient of variation was greater than 20%.**

Soybean Production Information

The Kentucky Cooperative Extension Service has a series of publications, “Soybean Production in Kentucky,” which contains a more detailed discussion of soybean production practices: Part I. *Status, Uses, and Planning* (AGR-128); Part II. *Seed Selection, Variety Selection, and Fertilization* (AGR-129); Part III. *Planting Practices and Double Cropping* (AGR-130); Part IV. *Weed, Disease, and Insect Control* (AGR-131); and Part V. *A Soybean Planting Rate Guide*, which is reproduced from this series and provided for your convenience (Table 2).

Oil and Protein Data

The protein and oil concentration data for all soybean varieties entered in the Kentucky Soybean Performance Tests are presented in Table 10. The Federal Grain Inspection Service is offering soybean oil and protein testing as official criteria for grade. At this time, the testing is optional. Soybean varieties differ in their protein and oil concentrations, which are influenced by the production environments. Because soybeans are grown primarily for oil and protein, these data are provided to indicate differences that exist between varieties produced in Kentucky.

Kentucky State Seed Law

The Kentucky State Seed Law requires all seed exposed, offered for sale, or sold in Kentucky to be labeled as to (1) kind and variety for each agricultural seed component present in excess of 5% of the whole and (2) the percentage by weight of each component. All soybean seed blends should be labeled as to the percentage of each variety that makes up the mixture. The term “variety unknown” may no longer be used in place of a variety designation for soybeans, as all soybean seed must be labeled by variety name.

Acknowledgments

In addition to the county agents and farm cooperators mentioned in Table 1, Thomas R. Stefaniak, David Pilcher, and Brenda Ward have contributed greatly to the production of this publication. Also the SCN lab at Princeton, Debbie Morgan and Don Hershman were important in the production of this publication.

Selection Key: <http://www.ca.uky.edu/agc/pubs/pr/pr424/pr424.pdf>

This new feature of the 1999 Kentucky Soybean Performance Test Web site allows subsets of Table 3, "Summary: Variety Test Tables 4-7." This sorting of the data in Table 3 provides alternative views of the data to show those varieties that are selected by basic questions a soybean producer might ask. For example: if a soybean producer is interested in Roundup Ready SCN-resistant varieties, click the 'Roundup Ready' box connected to the SCN variety box.

~ Roundup Ready variety

* Resistant to the soybean cyst nematode (Race 3)

** Resistant to the soybean cyst nematode (Race 3 and Race 14)

^A Within a maturity group, shaded yields are not significantly different (0.10 level) from the highest yielding cultivar (bold data) of that maturity group and year column.

Yield data are from the following counties (some with missing maturity groups from 1999, see tables 6 and 7):

1999 Fayette, Caldwell, Daviess, and Logan counties

98-99 Fayette, Caldwell, Daviess, Logan, Hardin, and Calloway counties

97-99 Fayette, Caldwell, Daviess, Logan, Hardin, Calloway, Warren, and Ballard counties

~ Roundup Ready variety

A Within a maturity group, shaded yields are not significantly different (0.10 level) from the highest yielding cultivar (bold data) of that maturity group and year column.

B Pf-Pi represents SCN reproduction during the growing season. Changes in SCN populations are best gauged by following SCN egg development through the season. Pf is the SCN egg count at the end of the season. Pi is the number of eggs present at planting.

A positive number indicates an increase in the SCN population while a negative number indicates a decrease in the SCN population.

C Resistance to cyst nematode races as reported by the companies. Race 3 and Race 14 are the predominant races in Kentucky.

SUS—susceptible to SCN MS—moderately susceptible MR—moderately resistant

Note: Yield loss in soybeans caused by SCN is determined by the SCN population at planting, not the population at harvest.

A race test performed from this field in 1997 indicated the presence of SCN Race 3.

^A Variety protein and oil concentration was determined at the Logan Co. location and expressed on the basis of 13% moisture. The mean protein concentration was 36.4%, and the mean oil concentration was 17.4%.

~ Roundup Ready variety

* Resistant to the soybean cyst nematode (Race 3)

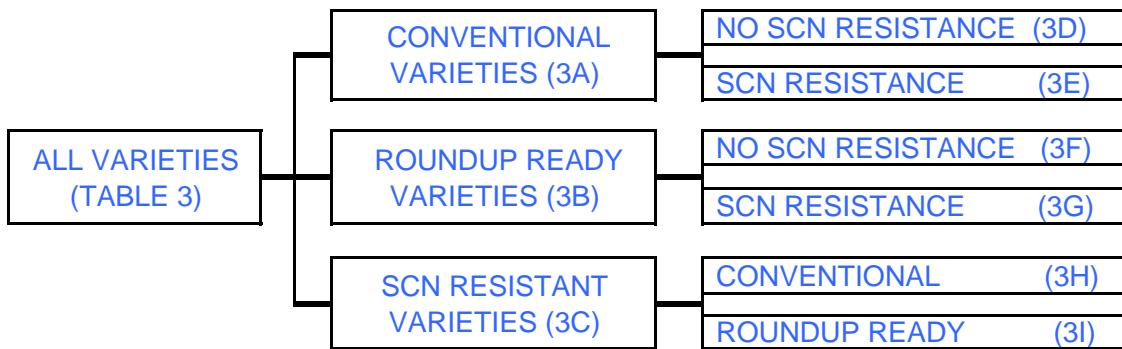

** Resistant to the soybean cyst nematode (Race 3 and Race 14)

The College of Agriculture is an Equal Opportunity Organization

Issued 12-99, 6000 copies

**SELECTION KEY TO CREATE SUBSETS OF TABLE 3
(1999 SUMMARY OF THE CONVENTIONAL TEST TABLES 4-7)**

Selected varieties found by using this key should also be found in the summary table containing all varieties (table 3) to observe potential yield loss by the chosen key restraints. The selected variety can be easily located in table 3 by finding it's 1999 yield in the appropriate maturity group.
